COMMITTEE REPRESENTATION

This Code of Practice was prepared under the supervision of the P 4509 Committee the Standards Council established under the Standards Act 1988.

The committee consisted of representatives of the following:

Nominating Organisation	Committee Member
BRANZ Ltd	Ed Soja
Department of Building and Housing	Alan Moule (Observer)
Fire Protection Association New Zealand Inc	Nigel Robinson
Ingenium	Eric Cawte
Insurance Brokers Association of New Zealand Inc	Peter Hughes
Local Government New Zealand	Logen Logeswaran
New Zealand Fire Equipment Association	David Hipkins
New Zealand Fire Service	Brian Davey
New Zealand Fire Service	Ian Millman
New Zealand Fire Service	James Firestone
New Zealand Water & Wastes Association	Johan Ehlers

ACKNOWLEDGEMENT

Standards New Zealand gratefully acknowledges the contribution of time and expertise from all those involved in developing this document.

Latest Revisions

The users of this Publicly Available Specification should ensure that their copies of the above-mentioned Standards are the latest revisions. Amendments to referenced New Zealand and Joint Australian/New Zealand Standards can be found on http://www.standards.co.nz.

Preface

As National Commander of the New Zealand Fire Service, I am pleased to release this revised code of practice for firefighting water supplies.

Those users familiar with the 2003 code of practice will see a number of changes that have resulted from comments and feedback from users of the document. The user will still be able to find tables that deal with fire hazard and specify the water flow requirements to match that hazard. There are now a number of worked examples included that help to understand the intent and application of the code and more detail relating to alternative firefighting water sources.

The code recognises the value of fixed fire protection systems, and particularly sprinkler installations, both in commercial structures and in homes. The Fire Service accepts that its firefighting water requirements can be tailored to a much lower demand in these structures. This edition of the code provides clearer guidance on what constitutes an alternative water supply where there is no reticulated supply, or where the available supply is insufficient for firefighting. The code has quantified firefighting water requirements based on sound engineering principles.

Taken together, these features provide the opportunity for all users to match firefighting water supplies to hazard, and to consider a range of alternatives in changing the water supply or changing the hazard in that process.

As an organisation we are committed to a process of continuous improvement, and this code is no exception. I welcome feedback and have already put a team in place that will work towards the next generation of this code of practice in coming years.

Mike Hall
National Commander New Zealand Fire Service
31 July 2008

Foreword

This code of practice was developed to provide direction on what constitutes a sufficient supply of water for firefighting in urban fire districts. This includes areas covered by any agreements under sections 38 or 39 of the Fire Service Act 1975. This code of practice is not intended to provide specifications for the water supply required for the effective operation of fire protection systems.

It is intended that the code of practice will form the basis of a partnership between the New Zealand Fire Service, territorial authorities, water supply authorities and developers so that the code may be used as a basis for territorial authority and water supply authority (WSA) conditions of supply or be called up, for example, by territorial authorities in rules regulating subdivisions in the district plan.

This code of practice is published under section 30(3) of the Fire Service Act.

Review

Suggestions for improvement of this code of practice will be welcomed. They should be sent to the National Commander, New Zealand Fire Service, PO Box 2133, Wellington.

1 GENERAL

1.1 Aims

This code of practice sets out what constitutes a sufficient minimum supply of water pressure and volume for firefighting in structures in urban fire districts. This includes areas covered by any agreements under section 38 or 39 of the Fire Service Act. Compliance with this code of practice does not guarantee that in each and every case the Fire Service can control or extinguish a fire with the water supply available.

The Fire Service recommends the installation of automatic fire detection devices such as smoke detection systems and fire protection systems such as sprinklers in buildings (irrespective of the water supply) to provide maximum protection for life and property.

Fire districts may have a range of water supply systems such as a fully reticulated water supply system (an urban water supply area), a rural water supply system that feeds a supply tank (a rural water supply area), or a stand-alone tank supply using rain water or a local well or bore for maintaining its contents.

Many areas outside fire districts will normally only have a rural water supply system or a stand-alone tank supply (although there may be some private reticulated water supply systems).

Where this code identifies firefighting water supply requirements for any of the three water supply systems above, these requirements can be used to provide advice for similar systems outside fire districts, that is, in rural areas.

In rural areas there may be water supply systems without firefighting capability. In many cases these systems are not sufficient for fire sprinkler systems unless stand-alone water supplies are provided. These are matters to be considered at the design stage of the sprinkler system.

In rural areas, the effectiveness of a water supply for firefighting is affected by the time and distance from a fire station, the fire loading in the structure, the speed of fire development, ready access to a sufficient quantity of water, and the seasonal sustainability of the water supply. Because structures remote from a fire station are significantly more at risk from fire outbreak, the Fire Service strongly recommends that sprinklers are installed in all structures (and specifically houses) sited more than a 10-minute response time from a fire station.

Property owners need to be aware that when considering fire risk, the provision of a readily available sufficient water supply will affect the extent to which a firefighting resource can save life and property. Should a fire occur, the Fire Service will still respond if called and will commence firefighting operations using whatever water is available, but delays in accessing a water supply allow a fire to continue to develop, to a size that more often results in a complete loss.

This code of practice defines the term firefighting water supply as, among other things, a supply of sufficient duration. Water supplies that are not of a duration considered sufficient by the Fire Service are still suitable for fighting fires. However they will not be classed as a firefighting water supply because in the opinion of the Fire Service they may not provide sufficient water to be able to mount an attack on a well-developed fire. The available water may be sufficient for a defensive fire attack aimed at preventing fire spread rather than rapid extinguishment.

Appendix B is intended to give guidance to territorial authorities, developers, and property owners on how water can be used to provide alternative firefighting water sources that the Fire Service can use in the event of a fire. The approach taken in this document is based on fire engineering principles using options for either a prescriptive or specific engineering solution.

This code of practice provides techniques to define a sufficient firefighting water supply that may vary according to circumstances. It relates to the Fire Service requirements only; territorial authorities and building owners may choose to exceed the provisions. SNZ PAS 4509 is written in a way that will encourage flexibility and provide different options for developers and territorial authorities.

This code of practice does not provide specifications for the total water supply required for the effective operation of fire protection systems that may be installed to protect structures or properties. Requirements for fire protection systems may vary and are dependent upon the system design parameters. Fire protection system water requirements must be considered in addition to firefighting water supplies (FW2 – see table 2) except for special or isolated cases (see Appendix C for guidance). If there are other users in the vicinity of the premises, then to comply with this code, it must be shown that all reasonable and appropriate steps have been taken to ensure that their expected usage has been taken into consideration in applying this code.

NOTE – Where a change of building use occurs, the existing water supply system should be evaluated against the requirements of the changed use and if there is a serious mismatch in requirements, this should be brought to the attention of the WSA and building owner.

1.2 Legal context

This code of practice is published under section 30(3) of the Fire Service Act. The code of practice is intended to assist the National Commander of the New Zealand Fire Service to carry out the duties specified in section 30(2) of the Act.

This code of practice is non-mandatory but could be incorporated into relevant bylaws under section 146(b) of the Local Government Act 2002 or district plans prepared under the Resource Management Act. It may also be referenced in New Zealand Standards and other Standards.

In doing so, the body incorporating the code must make a clear distinction between the obligation on the territorial authority and the water supply authority (WSA) to supply the water and the requirements (if any) placed on third parties to enable the respective authority to meet that obligation.

Section 92(2) of the Fire Service Act enables regulations to be made specifying requirements for fire hydrants. However, the National Commander considers that including guidelines on these requirements in this code of practice will be a more cost effective method for achieving appropriate standards through voluntary compliance. Regulations will only be resorted to if the guidelines in this code prove to be ineffective in achieving compliance.

In making decisions on water supplies, local authorities must consider the requirements of all relevant legislation. The main requirements are listed below.

1.3 Legislative requirements of territorial local authorities

1.3.1 Local Government Act

1.3.1.1 *Summary overview*

Under the Local Government Act 1974, territorial authorities are required to install fire hydrants, and to keep them charged.

The requirement to install fire hydrants is contained in section 647 of the Local Government Act 1974, which requires territorial authorities to provide fire hydrants on all reticulation water mains in such convenient places as it determines for extinguishing any fire, or in any fire district under section 26 of the Fire Service Act, as the New Zealand Fire Service Commission approves.

The requirement to keep pipes charged on which hydrants are fixed is contained in section 648 of the Local Government Act 1974.

Appendix D sets out the requirements of sections 647 and 648 of Part 39 of the Local Government Act 1974, and section 26 of the Fire Service Act.

1.3.1.2 *Interpretation*

Section 647 of the Local Government Act 1974 puts hydrants in two classes. The first relates to reticulations inside urban fire districts. Inside urban fire districts fire hydrants must be fixed in the water main pipes where a water supply is provided under section 130 of the Local Government Act 2002 as the New Zealand Fire Service Commission approves. SNZ PAS 4509 is a means of compliance with the Fire Service Commission's requirements.

NOTE – Section 130 of the Local Government Act 2002 does not apply to private water supplies.

The second group relates to reticulations outside urban fire districts. Fire hydrants must still be fixed in the water main pipes, but in this case it is the council that determines where they are installed. It is conceivable that some rural water supplies may have no firefighting capability at all.

1.3.2 Building Act

Section 18 of the Building Act states that building work must comply with the requirements of the New Zealand Building Code, and no more, unless expressly provided for in any other Act.

Section 46 requires copies of certain building consents to be provided to the Fire Service Commission, and under section 47 the Commission can offer advice on matters relating to provision for means of escape from fire, and could include firefighting water supplies. See Appendix E for more information on building consent documentation.

1.3.3 Resource Management Act

Territorial authorities control development and land use through their district plans, made under the Resource Management Act. Resource consents can include conditions that firefighting capability and fire hydrants are provided, but only insofar as the resource consent process allows. Matters that can be considered are those contained in the District Plan, the resource consent application, and in submissions.

1.3.4 Bylaws

Territorial authorities can make bylaws to manage water supplies. NZS 9201.7 provides a means by which local authorities determine urban water supply areas and rural water supply areas.

1.4 Interpretation

Clauses prefixed 'C' and printed in italic type are intended as comments on the corresponding clauses. They are not to be taken as the only or complete interpretation. This code of practice can be complied with if the comment is ignored.

2 DEFINITIONS AND ABBREVIATIONS

2.1 Definitions

Words and phrases used in this code of practice that are defined in the Fire Service Act have the same meanings as defined in the Act.

Additional water	Remaining half of total stipulated firefighting water within 270 m of (main entrance into) structure
Alternative firefighting water source	A non-reticulated supply available for firefighting meeting the requirements outlined in Appendix B
Approved Standard	A Standard listed in Appendix F
Approved tester	A person authorised by the water supply authority or the National Commander as competent to conduct measurements of flow and pressure, to test the adequacy of firefighting water supplies
Building Consent Authority	A Building Consent Authority as defined in the Building Act 2004 and includes a Territorial Authority or a private body acting within the scope of their approval
Couplings	See Fire Service coupling
Distance (from a fire hydrant or alternative firefighting water source)	Distance is measured from the fire hydrant or alternative firefighting water source to the main entrance of the building or structure, or as agreed with the Fire Region Manager
Dynamic pressure	See Running pressure
Extra high hazard	Commercial and industrial occupancies having high fire loads NOTE – Taken from NZS 4541 which provides further information.
Extra light hazard	Non-industrial occupancies where the amount and combustibility of the contents is low NOTE – Taken from NZS 4541 which provides further information.
Firecell	Has the same meaning as in the New Zealand Building Code, Clause A2

Fire district	See Urban fire district
Firefighting water supply	Supply of water, available to the Fire Service for firefighting, that complies with this code of practice; where reticulated, the required flow of water is at a minimum running pressure and of sufficient duration
Fire hazard	The danger of potential harm and degree of exposure arising from: (a) The start and spread of fire; and (b) The smoke and gases that are generated by the start and spread of fire
Fire hazard category	The number (graded 1 to 4 in order of increasing fire severity) as defined in the Compliance Documents for the New Zealand Building Code, Acceptable Solution C/AS1
Fire hydrant	An assembly usually contained in a pit or box below ground level and comprising a valve and outlet connection from a water main, to permit a controlled supply of water for firefighting. A pillar upstand connected to a water main and fitted with a valve and instantaneous coupling(s) adaptor will also constitute a fire hydrant. This does not include ball-type fire hydrants
Fire protection system	Includes detection, alarm, and suppression systems installed and maintained for on-going compliance with approved Standards
Fire Service coupling	Fittings or devices conforming with the Standard(s) listed in Appendix F3 that permit the connection of fire hose or firefighting waterway equipment to a source of water supply
Hardstand	A hard (roading) surface capable of withstanding the fully laden weight of a fire appliance from which fire operations for a structure are conducted. The size of a hardstand must include sufficient room for the fire appliance to enter, exit and manoeuvre and for firefighters to move around it to connect hose and safely access equipment. In most cases the hardstand will be the main road if the structure is close to it

Indexed or key fire hydrant	A fire hydrant with flow characteristics that are representative of that part of the network. The criteria to determine an indexed or key fire hydrant are set out in G5.1
Local authority	As defined by section 5 of the Local Government Act 2002. A regional council or territorial authority
Ordinary hazard	Commercial and industrial occupancies involving the handling, processing and storage of mainly ordinary combustible materials unlikely to develop intensely burning fires in the initial stages NOTE – Taken from NZS 4541 which provides further information.
Peak demand	The water supply flow for domestic and commercial use as determined by the water supply authority
Private fire hydrant	A fire hydrant not owned by a water supply authority. Water from such a fire hydrant may be included in firefighting water supplies, if the fire hydrant complies with approved Standards and is sufficiently maintained
Residual pressure	See Running pressure
Required water flow	Half of total stipulated firefighting water within 135 m of (main entrance into) structure
Roof vent	A part of the building which can be relied upon to provide ventilation, mechanical or otherwise
Running pressure	The water pressure in a water main as measured at an adjacent fire hydrant when the fire hydrant in use is fully open
Rural water supply area	An area formally designated by a water supply authority as an area serviced by a reticulated water supply system that is intended to supply water for specified purposes via restricted flow supplies and/or on-demand supplies but not necessarily with a firefighting capability

Static pressure	The water pressure in a water main as measured when none of the fire hydrants are open
Territorial authority	A city or district council
Urban fire district	A fire district declared or constituted under section 26 of the Fire Service Act
Urban water supply area	An area formally designated by a water supply authority as an area serviced by a reticulated water supply system with a firefighting capability, that is intended to supply water to customers via on demand supplies
Water supply authority (WSA)	The operational unit of the Council responsible for the supply of water, including its authorised agent NOTE – Taken from NZS 9201.7 which provides further information.
Water supply classification	An index assigned to a group of fire hydrants or alternative firefighting water sources that meet the specifications contained in table 2

2.2 Abbreviations

The following abbreviations are used in this code:

CBD	Central business district
EHH	Extra high hazard
ELH	Extra light hazard
FH	Fire hazard
FHC	Fire hazard category
FW	Fire water classification number
HRR	Fire heat release rate
LTSA	Land Transport Safety Authority
pH	Measure of the acidity or alkalinity of water
NZFS	New Zealand Fire Service
OH	Ordinary hazard
PRV	Pressure reducing valves
RRPM	Raised reflective pavement markers
WSA	Water supply authority

3 SYMBOLS AND UNITS

The following general symbols and units are used in this code of practice together with others specific to certain applications:

Symbol	Quantity	Unit
A_{exp}	Surface area of adjacent firecell(s) and/or structure(s) exposed to a firecell involved in fire	m^2
A_{fuel}	Surface area of fuel	m^2
A_h	Area of horizontal opening	m^2
A_v	Area of vertical openings	m^2
H_v	Weighted average height of vertical openings.....	m
H_m	Vertical height from the mid-height of the window opening to the mid-height of the horizontal opening	m
M_{exp}	Required water flow rate to protect the exposure....	L/s
M_{fuel}	Mass of fuel in the firecell	kg
M_{water}	Water flow rate required for firefighting.....	L/s
t_{fire}	Fire duration.....	s
Q_{fire}	Smaller value of Q_{vent} or Q_{fuel} for a firecell	MW
Q_{fuel}	Rate of heat release from the fuel controlled fire	MW
Q''_{fuel}	Rate of heat release per unit area of fuel burning ...	MW/m^2
Q_{max}	Maximum rate of heat release from fire	MW
Q_{vent}	Rate of heat release from ventilation controlled fire	MW
ΔH_c	Fuel calorific value	MJ/kg

4 USE OF THE CODE OF PRACTICE

4.1 Application

Although this code of practice has been developed for urban fire districts, these provisions are also intended to provide a guide for minimum firefighting water to other areas.

This code of practice is for the use of territorial authorities, water supply authorities, and the Fire Service to establish the quantity of water required for firefighting purposes in relation to the fire hazard in premises located in urban fire districts and to provide guidance in rural areas. It can also be used by developers and property owners to assess the adequacy of the firefighting water supply to new or existing premises.

The code of practice is based on an assessment of the water supplies needed to fight a fire and to limit fire spread. The firefighting water supplies required to address the fire hazard may be established by use of tables, or by calculation (see 4.4).

For any premises, this code of practice establishes the minimum firefighting water supply that is required for the fire hazard. To comply with this code of practice it must be shown that this minimum supply is designed to be available at all times as far as practicable. If it is not then either the supply must be increased or the fire hazard in the premises must be reduced.

This code of practice provides for minimum flows for firefighting water supplies and makes recommendations on the level of domestic and fire sprinkler system demand that water reticulations should deliver concurrently with firefighting water.

Fire service personnel giving advice on firefighting water supplies must do so in accordance with this code of practice.

For planning purposes, the territorial authority or water supply authority may choose to provide a firefighting water supply in accordance with a water supply classification selected from table 1. Any deficiencies identified for particular premises would have to be remedied by increasing the firefighting water supply or reducing the fire hazard in order to meet the requirements of this code.

Under sections 647 and 648 of the Local Government Act 1974, territorial authorities are required to install fire hydrants, and to keep them charged. See 1.3 for further information.

4.2 Classification of water supply

The Fire Region Manager, in consultation with the WSA, shall establish the requirements of the reticulated water supply in accordance with table 2.

It is recommended that water supply systems be designed to provide 60% of annual peak demand in addition to the fire flow. Fire flows are derived from table 2 or by way of the calculation methods outlined in Appendix H and Appendix J.

4.3 Method for determination of firefighting water supply

Compliance with the requirements set out in tables 1 and 2 will meet this code of practice. Fire hazard categories are determined from the methods given in the Compliance Documents for the New Zealand Building Code, Clause C/AS1.

For isolated fire hazards in an area with a lower water supply classification, a risk assessment should be carried out to determine measures to mitigate the hazard or increase the water supply (see 4.4).

4.4 Method for calculation of firefighting water supply

Fire engineers or similar competent persons may use alternative methods, such as those detailed in Appendix H and Appendix J to determine firefighting water supplies. To comply with this code of practice, such alternatives must be submitted for approval to the person(s) nominated by the National Commander. The person(s) so nominated will approve these cases on confirmation that the method and calculations used are correctly applied.

Alternative methods will need to show that the calculated firefighting water supply makes allowances for tactical flow rates (that is, the amount needed above a theoretical amount to absorb the released heat for operational effectiveness).

uses, have an entry level of FW3.
[illegible] bulk fuel installations, timber yards, tyre dumps, wood chip stock piles, recycle depots, and marinas.
[illegible] structures less than 50 m^2 in floor area, the FW3 requirement may be reduced by up to 50% with the agreement of the Fire Region [illegible]ed to be covered by this comment are predominantly garages, sheds, and outbuildings.

Table 2 – Method for determining firefighting water supply

Fire water classification	Reticulated water supply			Non-reticulated water supply	
	Required water flow within a distance of 135 m	Additional water flow within a distance of 270 m	Maximum number of fire hydrants to provide flow	Minimum water storage within a distance of 90 m (see Note 8)	
				Time (firefighting) (min)	Volume (m^3)
FW1	450 L/min (7.5 L/s) (See Note 3)	–	1	15	7
FW2	750 L/min (12.5 L/s)	750 L/min (12.5 L/s)	2	30	45
FW3	1500 L/min (25 L/s)	1500 L/min (25 L/s)	3	60	180
FW4	3000 L/min (50 L/s)	3000 L/min (50 L/s)	4	90	540
FW5	4500 L/min (75 L/s)	4500 L/min (75 L/s)	6	120	1080
FW6	6000 L/min (100 L/s)	6000 L/min (100 L/s)	8	180	2160
FW7	As calculated (see Note 7)				

NOTE –

(1) Table 1 lists the minimum requirements for firefighting water supplies. In developing towns' main reticulation systems, a water supply authority needs to cater for domestic/industrial water usage in addition to the above. This procedure is outlined in Appendix K.

(2) Special or isolated fire hazards which have higher requirements in an area of lower water supply classification must determine measures to mitigate the hazard or increase the water supply (see 4.4).

(3) Where houses have a sprinkler system installed to an approved Standard, the distance to a fire hydrant or alternative water supply may be negotiated by agreement with the Fire Region Manager.

(4) The water requirements for fire protection systems must be considered in addition to the firefighting water supplies, as detailed in table 1 (FW2), the fire protection system demand plus 1500 L/min (25 L/s) at 1 bar residual pressure.

(5) The minimum flow from a single hydrant must exceed 750 L/min (12.5 L/s), except for those cases where a home sprinkler is installed, in which case the minimum is 450 L/min (7.5 L/s) while the maximum design flow, for safety reasons, is limited to 2100 L/min (35 L/s).

(6) If the minimum water storage requirement as listed in the above table is not available from the reticulated system (reservoir), water can be sourced from an 'alternative supply' as approved by the Fire Region Manager. This water supply must always be within 90 m of the fire risk.

(7) FW7 is for either special or isolated hazards or where the fire hazard due to the size of the largest firecell and its fire hazard category make specific fire engineering assessment necessary. Appendix H and J must be used as the basis for calculating this required firefighting water supply.

(8) See Appendix B.

Commentary to table 2

Example 1

A subdivision is planned for the provision of light industrial buildings all on individual 1000 m^2 sections as zoned in the Council's District Plan. What firefighting water (for the purposes of sizing the water main) is required to be provided to these at present vacant sections assuming that none of those buildings are intended to be sprinkler protected?

Solution

The answer to this depends principally on the size of the largest firecell of the buildings which will be built, most of which will likely be a single firecell, but as this isn't known at this stage of the land development some estimate must be made. If one assumes that on a 1000 m^2 section building is likely to cover between 40% to 79% of this area, then the buildings are approximately at least 400 m^2 to 790 m^2 in size, and for light industrial most likely of Fire Hazard Category 3 (FHC3). Therefore they require a firefighting water supply of FW5 as determined from table 1.

The territorial authority or water supply authority thus decides that the installed inground reticulated water main must supply (just for the purposes of firefighting alone) 9000 L/min (150 L/s). If any buildings subsequently built exceeded this FW5 criterion then either the building could have a sprinkler system installed, or be compartmented into smaller firecells (to reduce the FW classification), or the water main would need to be upgraded, or a water storage tank appropriately sized and positioned on site to make up the shortfall. As an example say a FHC4 building was proposed some years later at a size of 650 m^2. This requires a FW6 classification which is 12 000 L/min (200 L/s).

Therefore either the main is required to be upgraded to meet this or the 180 minutes of expected firefighting at the shortfall of 3000 L/min (50 L/s) means a (180 min x 3000 L/min (50 L/s)) 540 000 L water storage tank is positioned on a site suitably placed to enable Fire Service vehicular access with suitable couplings for direct Fire Service connection.

Example 2

A FHC4 building of size 800 m^2 requires a FW6 classification as assessed from table 1, but is located in an area that only supplies a reticulated water supply capable of supplying FW5. If upgrading of the water main is impractical at this stage the options are:

(a) Install an approved automatic fire sprinkler system which drops the FW classification to FW2;

(b) Divide the building into firecells no larger than 199 m^2, which then only require a FW4 classification; or

(c) Install on site (with the approval of the Fire Region Manager) the shortfall of firefighting water as determined by the firefighting time of 180 minutes x [12 000 L/min (200 L/s) (FW6) – 9000 L/min (50 L/s) (FW5)] which equals 540 000 L.

4.5 Assessment

Appendix H describes a method for determining the maximum fire size in a structure.

Appendix J describes a method for assessing the adequacy of the firefighting water supply to the premises.

Where the available water supply meets or exceeds the required firefighting water supply, the water supply may be assumed for the purposes of section 30(2) of the Fire Service Act to be sufficient.

Where the available water supply is insufficient for firefighting purposes, steps must be taken either to improve the supply or reduce the maximum fire size. Use of Appendix H and Appendix J will indicate the options available in a particular situation.

4.6 Recording of water requirements

Where firefighting water requirements are determined using Appendix H and Appendix J, the Fire Service and the WSA shall keep records of the calculated values.

5 RUNNING (DYNAMIC) PRESSURE

The Fire Service controls water flow from water mains using the pumps on the fire appliance. The minimum running pressure in the water main should not be less than 100 kPa while the water main is flowing the required amount of water from the maximum number of fire hydrants. The minimum running pressure is also known as the residual pressure.

Due to the bore size of a standpipe, the maximum safe flow for design purposes (assuming pressure in the street water main is not a limiting factor) from a hydrant/standpipe assembly is 2100 L/min (35 L/s). Therefore if a structure risk required a firefighting water supply of 6000 L/min (100 L/s), then no less than three hydrants should be located (preferably as a hydrant group) in close proximity to the hardstand.

NOTE – For health and safety, and operating reasons, the Fire Service specifies a maximum working pressure for layflat hoses of 1050 kPa.

6 FIRE SERVICE VEHICLE ACCESS TO WATER SOURCE

6.1 Background

The adequacy of a firefighting water supply includes not only an assessment of the water supply that must be available, but also the location, connections, marking, and access to fire hydrants to enable the water supply to be used.

Roading widths, surface, and gradients where hydrants are located should support the operational requirements of Fire Service appliances. The Compliance Documents for the New Zealand Building Code specify these requirements and have final authority, but in general the roading gradient should not exceed 16%. The roading surface should be sealed, and trafficable at all times. The minimum roading width should not be less than 4 m. The height clearance along access ways (for example trees, hanging cables, and overhanging eaves) must exceed 4 m.

6.2 Fire hydrant location

The location of fire hydrants must follow the provisions contained in Appendix L. This code of practice does not necessarily require fire hydrants to be spaced at regular intervals on water mains.

6.3 Uncharged water mains

The WSA should advise the Fire Service as soon as practicable when new water mains are charged and commissioned or existing water mains are decommissioned and when reinstated either temporarily or permanently. Fire hydrant boxes, lids, markings, and marker posts must be removed from abandoned water mains.

NOTE – It is advised that the building owners should inform the insurers if a water main is uncharged for more than 12 hours.

6.4 Hardstand requirements

For a fire appliance to be effective it needs to be able to park in an area as close as possible to both the available water supply and the structure to be protected. This area is termed the 'hardstand'. For the standard fire appliance this area should not be less than 4.5 m in width by 11 m in length. However, given that the turning circle for this appliance is approximately 17.5 m all reasonable effort should be made to meet this length.

NOTE – An aerial fire appliance has a turning circle of 24.5 m and needs a width of 6 m to enable the stabilising struts to be deployed.

6.5 Access to alternative firefighting water sources

Where a sufficient firefighting water supply cannot be obtained solely from a reticulated supply, certain provisions must be followed to ensure the accessibility and usability of alternative firefighting water sources for firefighting purposes. These provisions are set out in Appendix B.

7 INSPECTION AND TESTING OF FIRE HYDRANTS

The Fire Service Act allows for the Fire Service to check, in any urban fire district, or in any area concerning any property that the Fire Service is under an obligation to protect pursuant to section 38 or section 39 of the Fire Service Act, the adequacy of firefighting water supplies, including volume and pressure in any water main, and to advise the WSA as to their sufficiency or otherwise. A best practice guide for the inspection of fire hydrants and the testing of firefighting water supplies is given in the Fire Service training note *Flow testing of water mains and hydrant inspections*. (See also Appendix G.)

Where a firefighting water supply is from private fire hydrants and water mains, an inspection and testing programme of fire hydrants must be agreed between the owner of the premises and the approved tester in accordance with Appendix G.

8 FIRE PROTECTION SYSTEMS

Fire protection systems protecting premises must comply with approved Standards, including testing and maintenance regimes, if their use is to be included in the assessment of fire hazard as set out in Appendix H. A list of approved Standards is provided in Appendix F.

9 DISPUTES

In the event of a dispute about the application or interpretation of this code of practice, any party to the dispute may refer the dispute to the Fire Service National Commander in writing. The National Commander may determine the matter in dispute in any manner the National Commander considers appropriate. In making a decision on the dispute, the National Commander will follow a process that is fair and reasonable in the circumstances (including providing an opportunity for all affected parties to be heard). When making a decision on a dispute the National Commander will give reasons for the decision.

APPENDIX B – ALTERNATIVE FIREFIGHTING WATER SOURCES

B1 Use of alternative firefighting water sources

Where reticulated water supplies are unavailable or insufficient, alternative firefighting water sources may be used to provide a firefighting water supply. Alternative sources may come from a mixture of reticulated and static supplies.

Alternative firefighting water sources should meet minimum standards for firefighting (access, security, visibility, adequacy of supply) and have a suitable fire service coupling for firefighting equipment and be sited to provide safe and ready access for Fire Service operations.

NOTE – Where plastic tanks are used for storing firefighting water, consideration needs to be given to shielding them from the effects of radiated heat from a fire.

Where this code of practice is applied in areas outside urban fire districts, Fire Service personnel giving advice on the adequacy of water volumes should take into account any special circumstances such as distance to the nearest fire station, size of buildings and normal use of water from any storage tank when recommending total storage volume.

B1.1 *Security*

The water supply must be reasonably protected from vandalism and tampering that may negate it being usable, for example, with a locked off (with a lightweight chain) valve on the outlet pipe that can be cut with bolt cutters to access.

B1.2 *Firefighting access*

There should be unimpeded access within the specified 90 m distance to a building allowing vehicular access to the firefighting water supply at all times, with the roading able to support a 20 tonne vehicle. In making an allowance for access, consideration must be taken of the complete travel route and access way widths, entry and exit ways, room to manoeuvre, obstructions (overgrown vegetation, hanging cables and building projections), gradients, gateways, and road surfaces. Where, due to the siting of the water tank, vehicle access is not practical, there should be a clear, safe working area, to support the siting of a portable pump and associated equipment, providing agreement is obtained from the Fire Region Manager.

APPENDIX J – WATER EXTINGUISHING CAPABILITY

J1 Introduction

This Appendix outlines the method of calculating the extinguishing capability of the available water and hence the required firefighting water supply. For information on capped fire size, see figure H1.

J2 Step 1 – Maximum fire heat release rate

Take value for Q_{max} derived from Appendix H.

J3 Step 2 – Calculate water flow required for firefighting

Calculate water flow required for firefighting

$M_{water} = 0.58\ Q_{max}$ (L/s) .....(Eq. J1)

(Answer J1)

where

Q_{max} is the maximum rate of heat release from fire (MW)... (Answer J4)

M_{water} is the water flow rate required for firefighting (L/s)

J4 Step 3 – Calculate exposure protection

Additional water is required to protect other structures from a fire in the structure under consideration. This is called exposure protection. The calculation for the protection of exposures is necessary where any exposed surface on an adjacent structure can be affected by radiation.

An exposed surface is defined as any external cladding on an adjacent structure that is combustible or coated with a combustible coating. An exposed surface is affected by radiation where the surface is within the horizontal distance calculated in accordance with the Compliance Documents for the New Zealand Building Code, Part 7, C/AS1.

As these distances have been derived for timber cladding, where plastic claddings and substrates have been used, add another 10 m to the distances derived above.

$M_{exp} = A_{exp} . \phi$ (L/s).....(Eq. J2)

(Answer J2)

where

M_{exp} is the required water flow rate to protect the exposure (L/s)

A_{exp} is the surface area of adjacent firecell(s) and/or structure(s) exposed to a firecell involved in fire (m^2)

ϕ is known as the water wetting rate and = 0.1 ($L/s/m^2$)

J5 Step 4 – Calculate total water flow required

The total water flow rate required M_{tot} is therefore:

$M_{tot} = M_{water} + M_{exp}$ (L/s) .....(Eq. J3)

M_{tot} = Answer J1 + Answer J2 ..... (Answer J3)

J6 Step 5 – Assess the adequacy of the available firefighting water

$M_{measured}$ is the measured flow rate recorded from flow tests conducted in accordance with Appendix G. The total firefighting water available $M_{available}$ may be sourced from reticulated and/or static supplies. To reflect the difference in accessibility and reliability of different sources of water supply, divide the measured flow rate from the source by the appropriate coefficents from table J1 and table J2 to obtain the available water flow, $M_{available}$.

$M_{available} = M_{measured} / C_1.C_2$ .....(Eq. J4)

(Answer J4)

In the case of firefighting water supplies from several different sources, add the individual available supplies together to come up with a cumulative value for $M_{available}$.

Table J1 – Water accessibility coefficient C_1

	Reticulated fire hydrants marked	Static supply, flooded instantaneous coupling	Static supply, flooded suction	Static supply, no coupling suction	Tanker or relay (no supply within 270 m)
C_1	1	1.15	1.25	1.5	2

Table J2 – Water reliability coefficient C_2

	Networked gravity	Dual system static/pump	Pump with emergency backup	Pump with no emergency power backup
C_2	1	1.1	1.1	1.5

If $M_{tot} > M_{available}$ = Failure

then it is necessary to reassess the fire safety features of a structure or improve the water supply.

If $M_{tot} < M_{available}$ = Pass

then there is a sufficient firefighting water supply.

J7 Access to firefighting water

Where the required firefighting water supply is available from fire hydrants then these must be located as given in table J3. Where firefighting water supply is available from alternative firefighting water sources, then the Fire Service access to the alternative firefighting water source must comply with Appendix B.

J8 Duration of fire

The fire duration may be estimated conservatively from:

$$t_{fire} = (\Delta H_c \, . M_{fuel}) / Q_{max} \quad \text{.....(Eq. J5)}$$

(Answer J5)

where
t_{fire} is the fire duration (s)
M_{fuel} is the mass of fuel in the firecell (kg)

This time is used to estimate the firefighting water supply storage volumes.

Table J3 – Water flows from fire hydrants

Calculated firefighting water supply (Answer J3) L/min (L/s)	**Water flow required in a distance of 135 m** L/min (L/s)	**Additional water flow required in a distance of 270 m** L/min (L/s)	**Maximum number of fire hydrants to provide flow**	**Water storage volume in reservoir and/or from alternative water source** (L)
< 750 (12.5)	Calculated flow	Not applicable	1	Water flow (Answer J3 x fire duration = Answer J5)
750 – 1500 (12.5 – 25)	750 (12.5)	Remainder of flow	2	
1560 – 3000 (26 – 50)	1500 (25)	Remainder of flow	2	
3060 – 6000 (51 – 100)	Half of calculated flow	Half of calculated flow	4	
6060 – 12 000 (101 – 200)	Half of calculated flow	Half of calculated flow	8	
> 12 000 (200)	Half of calculated flow	Half of calculated flow	8	

APPENDIX K – WATER SUPPLY SYSTEM CLASSIFICATION

Tables 1 and 2 are well suited for determining firefighting water requirements for individual fire risks. However, the flow rates and storage volumes that reticulated water supply systems should be designed for should be assessed on the range of fire risks that can be present in any one reticulation zone. The purpose of this appendix is to give guidance to water supply system designers in determining the design firefighting flow rates and storage volumes for reticulated water supplies.

It is important to note that firefighting water requirements are IN ADDITION to the domestic/commercial/industrial water supply needs and fire sprinkler demand. When water for firefighting is provided from hydrants it must be at a pressure of not less than 100 kPa.

K1 Water supply classifications

K1. 1 *Background*

Firefighting water supplies can be classified using the scale shown in table 2, taking into account factors such as the size (firecell area) of the average fire risk and the highest expected fire risks in the area, and anticipated future development. Provision is also made for FW7, for which flow rates and storage requirements can be determined on a case by case basis, using methods such as those outlined in Appendices H and J.

Table 1 shows the fire water supply classifications that are required to protect individual fire risks.

K1. 2 *General procedure for establishing classifications for water supply reticulations*

The capacity of existing water supplies to store and deliver water for firefighting can be measured by undertaking comprehensive flow testing or estimated through computer modelling. Water supply authorities should undertake this work in partnership with the Fire Service. If necessary the WSA can establish water classification zones after consultation with the Fire Service, so that the minimum storage and flow requirements in the zones are clearly defined. Due to the capital intensive nature of water reticulations long lead times may be required to make improvements. Strategies should therefore be put in place in consultation with the Fire Service that clearly describe how any known deficiencies in the water supply are managed and how they will be remedied. Any consultations with the Fire Service should occur at the Fire Region Manager level or their delegated authority.

To determine the firefighting capacity for new water supplies in greenfield areas the WSA should make an assessment of the developments that are likely to occur in that area, and design the water supply system for the average fire risk using tables 1 and 2 taking account of other factors such as future growth after consultation

with the Fire Service. Any new developments should be assessed against the capacity of the water supply system, to ensure that developers design within the reticulated supply capacity, and in cases where the required fire water exceeds the reticulation capacity, remedy the effects by providing additional on site storage or increasing the reticulated capacity.

K2 Storage

The volume of storage that is reserved for firefighting purposes must not be used for normal operational requirements, see figure K1. Additional storage must be provided to balance diurnal peak demand, seasonal peak demand and normal system failures, for instance power outages. The intent is that there are always sufficient volumes of water available for firefighting, except during civil defence emergencies or by prior arrangement with the Fire Region Manager.

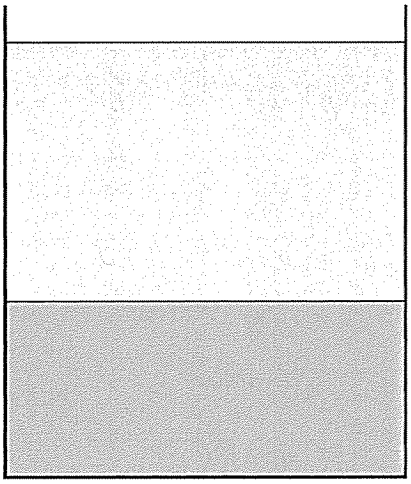

Figure K1 – Reservoir storage

K3 Flow

The flow rate that is available for firefighting from hydrants can be measured by undertaking comprehensive flow tests or be estimated through network modelling.

Comprehensive flow tests should be carried out at times of reasonably high consumer demand (domestic, industrial, and commercial water usage) so that the test results will reflect the effects of any reduced reticulation pressure at such times. The timing for such tests must be determined in consultation with the water supply authority to manage any discolouration and reduced pressures that may result.

When the available firefighting flow rates are estimated by running computer models, it is necessary to include background consumer demand concurrently with the fire water flows from hydrants. As a guide, two thirds of the annual peak consumer demand should be used consecutively with fire flows from hydrants, with resulting reticulation pressures not less than 100 kPa. The annual peak

demand varies from zone to zone, but as a guide in residential areas, can be estimated as follows:

Zones less than 1000 dwellings: $Q_{peak} = 0.596D^{0.632}$ L/s

Zones larger than 1000 dwellings: $Q_{peak} = 0.0467D$ L/s

where Q_{peak} = Peak annual demand (L/s)

D = Number of dwellings

Individual water suppliers may use different formulae particular to their suppliers, based on observed peak flow rates.

In most cases several modelling runs would be needed to assess the impact of different fire scenarios at different locations, but scenarios should allow for only one fire at a time.

Where structures are fitted with compliant fire sprinkler systems, the required water supply classification is no greater than FW2. NZS 4541 requires the fire sprinkler flows to be delivered concurrently with a flow of 1500 L/min (25 L/s) from the nearest fire hydrants at the pressure determined as part of the sprinkler system design and flow tests. By default a flow test should therefore be available that takes into account the effect of reduced pressure due to consumer demand.

Computer modelling can be used to verify that the level of consumer demand at the time the flow test was conducted was at least two thirds of peak annual demand. In cases where the modelled pressure is less than the observed pressure, further work should be carried out to determine the appropriate available reticulation pressure that the fire sprinkler system should be designed for.

K3. 1 *Example*
A water reticulation has to be designed for a proposed business park. Average lot size will be 2000 m^2. Working/business/storage activities with medium fire load such as manufacturing, processing, and bulk storage up to 3 metres will be permitted under the proposed district plan provisions.

Using tables 1 and 2, the water supply qualifications and firefighting water requirements in table K1 are possible.

Table K1 – Example of calculating flow

Options	Building sprinklered	Firecell size (m^2)	Fire water classification	Flow rate from hydrants L/min (L/s)	Storage in reservoir (m^3)
1	Yes	UNLIMITED	FW2	1500 (25)	45
2	No	0 – 199	FW3	3000 (50)	180
3	No	200 – 399	FW4	6000 (100)	540
4	No	400 – 799	FW5	9000 (150)	1080
5	No	800 – 1199	FW6	12 000 (200)	2160
6	No	>1199	FW7	Specific design	

NOTE – The 'storage in reservoir' column is to ensure that the specified firefighting water is a dedicated amount purposefully allowed for in a town water reticulation design IN ADDITION to the domestic, commercial, and/or industrial needs. It is obtained by multiplying the expected firefighting duration by the required fire flow rate from the hydrants.

After consultation with the Fire Service and through the Resource Management process it is agreed to provide reticulated firefighting capacity for sprinklered buildings and for non-sprinklered buildings up to FW3. All buildings with firecells not greater than 199 m^2 can therefore be protected using water from the reticulated supply, but any proposal to construct a firecell larger than 199 m^2 will require a sprinkler system to be installed or on-site storage to be provided to make up the shortfall.

An example of the application of this is as follows:

If a non-sprinkler protected building whose largest firecell is 600 m^2 is to be built in this area it would have a FW classification of FW5. However the water reticulation network supplying this zone is only rated at FW3. Table K2 shows a comparison of the firefighting capacity of the water supply network with the firefighting water requirements for the fire risk.

Table K2 – Comparison of firefighting capacity of the water supply network with the firefighting water requirements

	Flow rate L/min (L/sec)	**Storage** (m^3)
Reticulation designed to meet FW3 requirements	3000 (50)	180
Fire risk FW5	9000 (150)	1080
Theoretical water supply system deficit	6000 (100)	900
Possible solutions to provide for flow and storage deficits	(a) Provide additional flow from on-site storage source (b) Check whether actual water reticulation capacity is higher than 50 L/s (c) Increase water reticulation capacity (d) Combination of the above	(a) Provide on-site storage (b) Check whether additional storage from the water supply reservoir can be dedicated for firefighting purposes (c) Increase water supply system storage volume (d) Combination of the above

APPENDIX L – SPECIFICATION, LOCATION, AND MARKING OF FIRE HYDRANTS

L1 Scope

The purpose of this Appendix is to provide a specification and a suitable system for marking the location of fire hydrants and water supplies so they can be readily identified by the Fire Service and, where necessary, by the general public. Fire hydrant installation is covered by NZS 4404.

L2 General requirements

Fire hydrants must comply with an approved Standard, see Appendix F.

Every fire hydrant must have its position identified by a combination of markings and indicators as set down in this code of practice. Fire hydrants should not be marked until the water main is commissioned, and markings must be removed if the water main is uncharged or abandoned.

NOTE – This clause does not apply if the water main is temporarily uncharged or decommissioned, in which case the Fire Service needs to be informed.

Road controlling authorities must approve any devices or markings installed in a road reserve. This includes any markings on the roadway and any markers or other devices installed beside the roadway.

L3 Forms of markings and indicators

L3.1 *Required markings for underground fire hydrants located on or adjacent to sealed roads*

The position of the underground fire hydrant must be identified by:

(a) The lid of the fire hydrant box painted with yellow paint; and

(b) An isosceles triangle of solid colour with 600 mm sides and 450 mm base, painted yellow, on or near the centre of the carriageway, with the apex pointing towards the underground fire hydrant; and

(c) In addition, a circle of 1.2 m outside diameter with a line width of 100 mm painted yellow as concentrically as possible around the underground fire hydrant, where, in the opinion of the person responsible to the WSA for the installation, maintenance, and marking of fire hydrants, access to the fire hydrant may be obstructed by parked vehicles.

See figure L1.

The paint used must comply with the requirements of TNZ M/07.

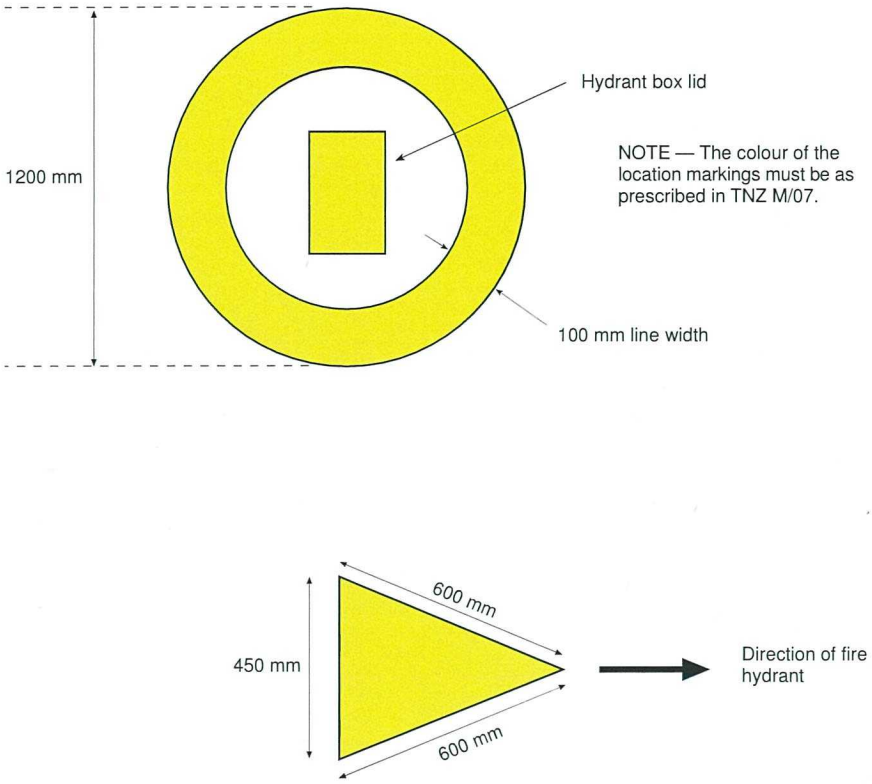

Figure L1 – Fire hydrant marking

L3.2 *Required markings for underground fire hydrants located on or adjacent to unsealed roads*

The position of the underground fire hydrant must be identified by:

(a) The lid of the fire hydrant box painted with yellow paint;

(b) An indicator plate or marker post in accordance with L3.4.

L3.3 *Required markings for outlets other than fire hydrants*

Other pressurised water outlets used for firefighting water supplies must be marked to the satisfaction of the National Commander.

L3.4 *Requirements for indicator plates or marker posts*

Where the fire hydrant location may be difficult to identify, or where it may be obscured by snow or vegetation, an indicator plate or marker post may be used.

If an indicator plate is used, it must comply with the requirements of BS 3251 except that the background colour (specified in 8.2 of BS 3251) must be yellow and comply with TNZ M/07.

The indicator plate must not be less than 600 mm and not more than 3 m above the road level and must be placed on or near a boundary line, wall or structure. Alternative siting may be used in exceptional circumstances subject to the approval of the Fire Region Manager.

If a marker post is used, it must comply with the dimensions specified for Type C edge marker posts in the Transit New Zealand *Manual of*

traffic signs and markings – Part II: *Markings*. The two yellow reflectors must be replaced with two blue reflectors and these must be repeated on the reverse side of the post so it will be visible from both directions. The post must be located in the same manner as the standard edge marker posts in relation to the trafficable portion of the carriageway and in line with the fire hydrant.

NOTE – Road controlling authorities must approve any installation of edge markers.

The road reserve between the carriageway and the indicator plate or marker post must be maintained so that the indicator plate or marker post is readily visible from the carriageway.

L3. 5 *Additional markings*

Any additional markings placed near an underground fire hydrant should not obliterate or confuse any of the markings set down in this code of practice, for example, markings to prohibit parking.

Where deemed necessary by the Fire Region Manager of the urban fire district or the WSA, the following additional markings may apply:

(a) Standard yellow post with FH marking;
(b) Kerb marking in yellow.

Additional marks may indicate:

(a) Fire hydrants installed on water mains with running pressure in excess of 1200 kPa;
(b) Fire hydrant that is the last one on a dead-end water main.

L3. 6 *Blue raised reflective pavement markers (RRPM)*

The use of RRPM on roads is controlled by road controlling authorities, therefore the use of these markers must be with their consent. The use of RRPM is recommended as additional means of identifying fire hydrant locations.

The Land Transport Safety Authority (LTSA) (now Land Transport New Zealand) has supported the use of blue RRPM through recent editions of the Road Code and has issued Traffic Note 25, that is sent to all local authorities and other organisations involved with roads. This notice allows for the use of RRPM for marking fire hydrant locations. Where they are used, they must be located close to, and on the fire hydrant side of, the centre of the roadway at or near the base of any yellow triangle marked on the surface. It is suggested in Traffic Note 25 that road controlling authorities prohibit the use of these blue RRPM for any purpose other than indicating fire hydrants.

NOTE – Traffic Note 25 allows the use of the blue RRPM, but does not make them compulsory.

L4 Location of fire hydrants

Where the required firefighting water supply has been calculated using Appendix J, the distance to fire hydrants is given in table J3, that is: 135 m for **required water** flow, with **additional water** within 270 m.

This maximum hydrant to structure distance is calculated as straight line segments along the road, main access path, or drive to the front door (main entrance). This is the 'as you would lay the hose' distance, which means that this path must be free from obstructions, smooth, and accessible at all times. See figure L2(a) and (b).

It is important to understand that firefighting water supply is most effective when targeted for a specific risk, so where a structure requires say 6000 L/min (100 L/s) of firefighting water, then (as each hydrant for design purposes cannot provide more than 2100 L/min (35 L/s)) these (minimum of three) hydrants should be grouped as close as reasonably possible to the 'hardstand' (for this structure). This hardstand is the pumping platform, from which firefighting operations will take place. If the structure is very large or the main entry point (front door) is located more than 18 m from the road's edge, a ring water main and/or grouped hydrants at the main entry points is the better solution. This will facilitate fastest Fire Service set-up and thus likelihood of fire control. See figure L2(c).

This code of practice focuses on how the most effective firefighting water supply can be provided for a structure. To be of practical use hydrants should be within 25 m (one hose length) of the hardstand and must be readily accessible for the fire appliance. However, in assessing where hydrants should be sited, each structure needs to be assessed based upon its location to the street frontage, which is most often where the NZFS hardstand for the structure will be. Thus the principal means of assessing this maximum distance of a fire hydrant (or fire hydrant group) from a structure (main entry point) is calculated by summing the straight line segments as the hose would be laid on an unobstructed surface, between them. See figure L2(c).

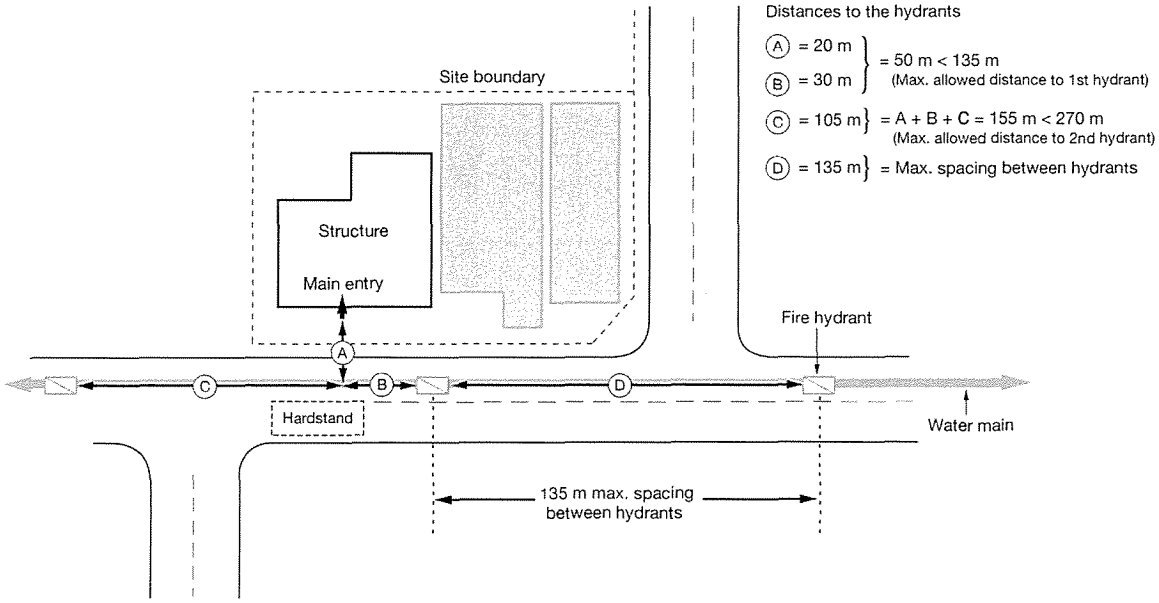
The recommended spacing between fire hydrants should not exceed 135 m. Where there are no premises to be protected, the spacing may be greater. To enable the required flow to be obtained from a water main, fire hydrants may be installed in groups in the same water main. The Fire Region Manager must approve the location and number of these grouped fire hydrants.

Fire hydrants must be readily accessible for fire appliances and should be ideally positioned near road or street intersections and not less than 6 m from any building structure to maintain a clear working space.

Existing fire hydrants may be found at the sides of buildings or structures, or within 6 m of them. These fire hydrants do not comply

with this code of practice but may be included in the calculation of firefighting water supply at the discretion of the Fire Region Manager of the urban fire district.

NOTE – For determining whether a building is in the specified distance to a fire hydrant (or water source), the 'as you would lay the hose distance' as measured from the main entrance to the building to the water supply, should be used. If as in a greenfields subdivision no building platforms have been specified, the value to be used to obtain the distance to the main entrance of the building should be not less than half the longest lot dimension. For example, a lot measuring 40 m x 60 m would require not less than 30 m to be added to the 'as you would lay the hose' distance.



NOTE – Notwithstanding meeting the **required** and **additional** distances to a hydrant, hydrant-to-hydrant spacing should not exceed 135 m.

Figure L2(a) – Code requirements for the location and spacing of fire hydrants (Example 1)

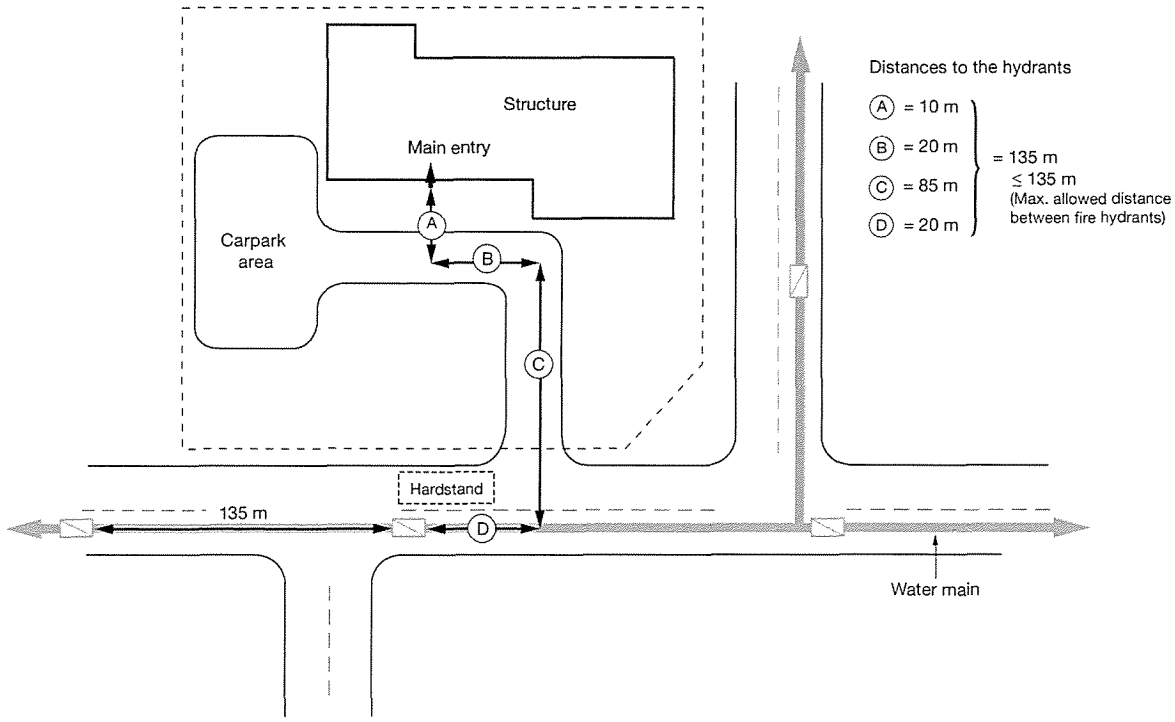


Figure L2(b) – Code requirements for the location and spacing of fire hydrants
(Example 2)

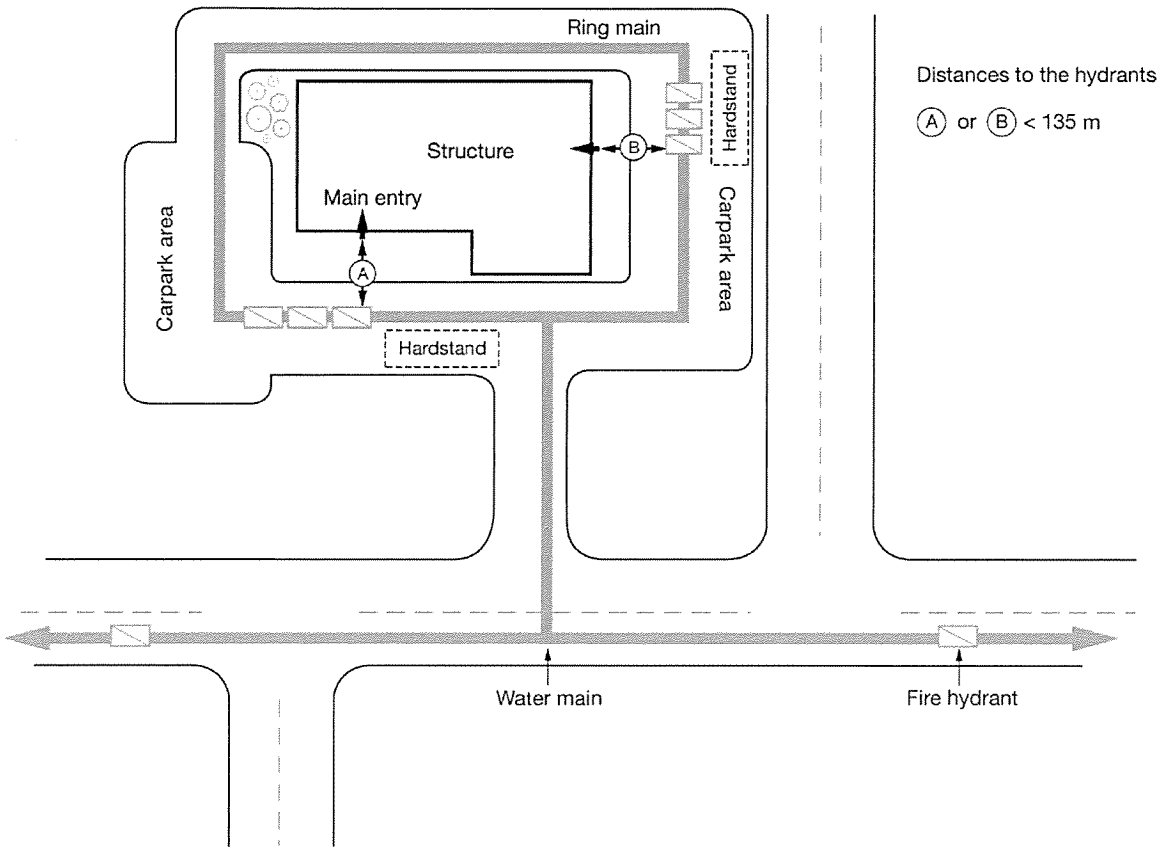

Figure L2(c) – Code requirements for the location and spacing of fire hydrants

Large structures more than 18 m from the road's edge with multiple entrances and large firefighting water supply requirements.
